## 1. Aims of the practise

- Get the reaction order with different reactants.
- Analyse the effect of a catalyst on the reaction's speed.
- Study the kinetics of the reaction bias the reaction of the generated $I^{-}$ with $\mathrm{S}_{2} \mathrm{O}_{3}{ }^{2-}$.

## 2. Theoretical Background

The reaction we will work with: $\quad \mathrm{S}_{2} \mathrm{O}_{8}{ }^{2-}+2 \mathrm{I}^{-} \rightarrow 2 \mathrm{SO}_{4}{ }^{2-}+\mathrm{I}_{2}$
The speed of the reaction can be written in different ways ${ }^{1}$ :

$$
v=-\frac{d\left[S_{2} \mathrm{O}_{8}{ }^{2-}\right]}{d t}=-\frac{1}{2} \frac{d\left[I^{-}\right]}{d t}=\frac{1}{2} \frac{d\left[\mathrm{SO}_{4}{ }^{2-}\right]}{d t}=\frac{d\left[I_{2}\right]}{d t}
$$

For any reaction, we can write the rate equation or rate law: the swiftness in which reactants turn into products:

$$
v=k\left[S_{2} O_{8}^{2-}\right]^{\alpha}\left[I^{-}\right]^{\beta}
$$

The addition of $\boldsymbol{a}$ and $\boldsymbol{\beta}$ is called reaction order. Those coefficients do not necessarily have to be the same as the stoichiometric coefficients. k is called reaction rate constant and it is specific for every reaction ${ }^{2}$.

${ }^{2}$ Notes from Kimika Orokorra II, 6. Ikasgaia: Zinetika kimikoa, 2018-2019 school year, Teacher: Marian Iriarte

If we put the reactants in these ratio: $\frac{\left[K_{2} S_{2} O_{8}\right]}{[K I]}=\frac{a}{2 a}$
So, whenever the reaction happens, a quantity $x$ of the reactants will be consumed and therefore the same quantity $x$ will be created ${ }^{3}$

| Reac. | $\mathrm{S}_{2} \mathrm{O}_{8}{ }^{2-}+2 \mathrm{l}^{-}$ | $\rightarrow 2 \mathrm{SO}_{4}{ }^{2-}$ | $+\mathrm{I}_{2}$ |  |
| :---: | :---: | :---: | :---: | :---: |
| Beg. | a | 2 a | - | - |
| End | $\mathrm{a}-\boldsymbol{x}$ | $2 \mathrm{a}-2 \boldsymbol{x}$ | 2 x | x |

So, replacing these values into the rate law:

$$
\frac{d x}{d t}=k(a-x)^{\alpha}[2(a-x)]^{\beta}
$$

${ }^{3}$ Kenneth A. Connors, "Chemical Kinetics: The Study of Reaction Rates in Solution", VHC, Madison (Wisconsin), ISBN: 3-527-21822-3

Consequently, depending on the values of $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ the reaction order will be different and so will be the integrated equation.

The objective of this class is to get these coefficients.
Generally, reactions have 4 possible orders ${ }^{4}$ :

- Order 0 if $[X]$ vs $t$ is linear.
- Order 1 if $\ln [X]$ vs $t$ is linear.
- Order 2 if $1 /[\mathrm{X}]$ vs $t$ is linear.

In order to determine the speed, it is necessary to know the concentration at different times of the reaction. To do so, we will have to take a sample of the reaction and titrate it.
${ }^{4}$ Paul Andersen (Bozeman Science) "The Rate of Reactions", Youtube

The reaction of the titration:

$$
2 \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}+\mathrm{I}_{2} \rightarrow \mathrm{Na}_{2} \mathrm{~S}_{4} \mathrm{O}_{6}+2 \mathrm{NaI}
$$

This way we will know the concentration of lodine in the sample we took.

The indicator for this titration will be starch. In contact with iodine, starch turns blue but on its own, $\mathrm{I}_{2}$ in water solution is yellow-brownish ${ }^{5}$.

But for having reliable data, we must stop the reaction. Recollecting these data at different times, we will be able to create the previously seen graphs.
${ }^{5}$ Notes from Kimika Analitikoa I, 2019-2020 school year, Teacher: Rosa García

Catalysts are compounds that considerably accelerate reactions. Their interest in industry and in other chemistry fields ${ }^{2}$.

Not only do they provoke the reaction to be swifter but they also diminish the necessary energy to start a reaction ${ }^{6}$.

Reaction Progress

## 3. Experimental Procedure

Reactants and material:

- $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$
- KI
- $\mathrm{K}_{2} \mathrm{~S}_{2} \mathrm{O}_{8}$
- $\mathrm{FeSO}_{4}$
- Starch
- $50 \mathrm{~cm}^{3}$ Volumetric Flask
- $50 \mathrm{~cm}^{3}$ Pipette
- $250 \mathrm{~cm}^{3}$ Frosted glass Erlenmeyer
- $100 \mathrm{~cm}^{3}$ Erlenmeyer
- Thermostatic bath

Two reactions will be carried out:
$1^{\text {st }}$ Reaction:

- Prepare $250 \mathrm{~mL} 0,01 \mathrm{M} \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}, 100 \mathrm{~mL} 0.05 \mathrm{M} \mathrm{KI}, 100 \mathrm{~mL} 0,025 \mathrm{M} \mathrm{K}_{2} \mathrm{~S}_{2} \mathrm{O}_{8}$
- Set the thermostatic bath at $40^{\circ} \mathrm{C}$. Heat KI and $\mathrm{K}_{2} \mathrm{~S}_{2} \mathrm{O}_{8}$ solutions.
- Put the frosted glass erlenmeyer in the bath and add 50 mL of the $\mathrm{K}_{2} \mathrm{~S}_{2} \mathrm{O}_{8}$ solution.
- Pour 50 mL of KI solution and start measuring time and stirring.
- Instantaneously take 10 mL into an Erlenmeyer and put it in the ice to stop the reaction. Add some starch and titrate it.
- Take a sample every 5 minutes and titrate it. You must have 6 samples before finishing.

$\underline{2}^{\text {nd }}$ Reaction:
- Prepare a 50 mL solution containing $0,02 \mathrm{M} \mathrm{KI}$ and $2 \times 10^{-3} \mathrm{M} \mathrm{FeSO}_{4}$
- Put that solution into the reaction flask and heat it until $40^{\circ} \mathrm{C}$.
- Add 50 mL of $0,01 \mathrm{M} \mathrm{K}_{2} \mathrm{~S}_{2} \mathrm{O}_{8}$ diluting the previously made solution. Heat it until $40^{\circ} \mathrm{C}$.
- Pour the $\mathrm{K}_{2} \mathrm{~S}_{2} \mathrm{O}_{8}$ into the flask containing $\mathrm{FeSO}_{4}$ and KI. Stir and start measuring the time.
- Instantaneously take 10 mL put it in the ice to stop the reaction, add the starch and titrate it
- Take 5 more samples, one every minute.

Afterwards, repeat the second reaction twice. One time with $\mathrm{FeSO}_{4} 4 \times 10^{-3} \mathrm{M}$ and the second time with $\mathrm{FeSO}_{4} 6 \times 10^{-3} \mathrm{M}$

Additionally, each group will make a reaction with a concentration of $\mathrm{FeSO}_{4}$ they want.

## 4. Data Collection and Treatment

During the experiment, we will have to measure both time and $\left[I_{2}\right]$ to later construct a graph and get the reaction rate constant.

We can deduce the $2^{\text {nd }}$ order rate law. Afterwards we will have to transform this equation to make it depend on the volume of $\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}$ consumed for the titration.

We will now build the graph to obtain the speed constant for the first reaction.
With the data of other groups for different catalyst concentrations calculate the catalytic constant at $40^{\circ} \mathrm{C}$ and check that the kinetic order for the catalyst is 1
